

# Approximated computation of atomic three- and four-electron integrals over $B$ -splines

Saito Shiro L.

## Abstract

Approximated computational methods of atomic three- and four-electron integrals over  $B$ -splines which appear in Hylleraas-CI calculations are presented. The present methods represent the three- and four-electron integrals to sums of products of two-electron integrals over the  $B$ -splines. Comparison of the three- and four-electron integral values computed using the approximated methods with those given by Ruiz [J. Math. Chem. 46, 24 (2009) and J. Math. Chem. 46, 1322 (2009).] showed relative errors of  $\sim 10^{-14}$ .

## 1. INTRODUCTION

In quantum mechanical calculations for atomic systems, atomic orbitals are usually expanded with the appropriate basis functions. The most commonly used basis functions is Slater-type functions (STFs) and Gaussian-type functions (GTFs). Unfortunately, their linear dependence sometimes disturbs the calculations. The use of  $B$ -splines<sup>1,2</sup> can avoid this problem. The  $B$ -splines of order  $K$  ( $B_{i,K}(r)$ ) are piecewise polynomials of degree  $K-1$  on a knot sequence in a cavity of radius  $R$ . The knot sequence  $\{t_i\}$  is a set of points defined on an interval  $[0, R]$ .  $B_{i,K}(r)$  is nonzero in the interval  $[t_i, t_{i+K})$ . The advantage of  $B$ -splines is that they are very flexible and are relatively free from computational linear dependence. It is possible to apply a common  $B$ -spline set to all atoms, irrespective of orbital symmetry, without loss of accuracy. Atomic calculations with  $B$ -splines yield highly accurate energies and properties<sup>3-5</sup>. Therefore, the development of the atomic calculation method with  $B$ -splines is very interesting and important.

To calculate accurate atomic properties, one must calculate wave functions which are considered

electron correlation effects. There are various computational methods for dealing with such the wave functions. In particular, the configuration interaction (CI) method is extensively used. A CI wave function is expressed with a linear combination of configurations state functions (CSFs). Although the CI method can easily account for static correlation effects, it is poor at accounting for dynamic correlation effects. To effectively consider the dynamic correlation effects, wave functions must include explicitly inter-electronic distances ( $r_{ij}$ ). Hylleraas-type method<sup>6</sup> is one of the methods and gives highly accurate energy of two-electron atoms<sup>7</sup>. Unfortunately, it is difficult to apply the Hylleraas-type method to many-electronic atoms because many-electron integrals are required. The many-electron integral for the  $N$ -electronic atom is generally written as

$$\iiint \cdots \int d\mathbf{r}_1 d\mathbf{r}_2 \cdots d\mathbf{r}_N A(\mathbf{r}_1) B(\mathbf{r}_2) \cdots C(\mathbf{r}_N) r_{12}^S r_{13}^t \cdots r_{N-1N}^u A'(\mathbf{r}_1) B'(\mathbf{r}_2) \cdots C'(\mathbf{r}_N), \quad (1)$$

where  $A, B, C, \dots$  are atomic functions. The many-electron integrals of many-electronic atoms are expressed in complicated formulas, which are generally difficult to calculate. There is a method that retains the advantages of the Hylleraas-type method and reduces many-electron integrals. This is the method combined the Hylleraas-type method and the CI method, and is called Hylleraas-CI method.<sup>8</sup> The Hylleraas-CI method usually deals with wave functions expanded in configurations containing at most one  $r_{ij}^s$ . Therefore, the Hylleraas-CI method requires only up to four-electron integrals, even for atoms with more than four electrons. The Hylleraas-CI method was first applied by Sims and Hagstrom to the Be atom.<sup>8</sup>

The three-electron integrals<sup>9-15</sup> and four-electron integrals<sup>9,16,17</sup> over STFs have been formulated by various authors. The formulas for the three- and four-electron integrals are complicated and computationally loaded. This remains true for the integrals over the  $B$ -splines. However, it is possible to avoid this computational difficulty using an approximated computational method of many-electron integrals proposed by Kutzelnigg and Klopper<sup>18</sup>. Their method approximates a many-electron integral to sums of products of two-electron integrals by incomplete set insertion, e.g.,

$$\begin{aligned} & \iiint d\mathbf{r}_1 d\mathbf{r}_2 d\mathbf{r}_3 A(\mathbf{r}_1) B(\mathbf{r}_2) C(\mathbf{r}_3) r_{12}^S r_{13}^t A'(\mathbf{r}_1) B'(\mathbf{r}_2) C'(\mathbf{r}_3) \\ &= \sum_i \iint d\mathbf{r}_1 d\mathbf{r}_2 A(\mathbf{r}_1) B(\mathbf{r}_2) r_{12}^s \psi_i(\mathbf{r}_1) B'(\mathbf{r}_2) \\ & \quad \times \iint d\mathbf{r}_1 d\mathbf{r}_2 \psi_i(\mathbf{r}_1) C(\mathbf{r}_2) r_{12}^s A'(\mathbf{r}_1) C'(\mathbf{r}_2), \end{aligned} \quad (2)$$

where  $\{\psi_i\}$  is an incomplete set. If  $\{\psi_i\}$  are expanded with flexible basis functions, Eq.(1) may yield highly accurate values. The  $B$ -splines are suitable for this approximation method.

Our purpose in this work is to formulate many-electron integrals over the  $B$ -splines which appear in Hylleraas-CI calculations using the approximation method and to check the accuracy of the resulting approximated formulas. There are many formulations and calculations of many-electron integrals. Most of them are for the integrals over the STFs. We check the accuracy of the approximated formulas by transforming the  $B$ -spline many-electron integrals into the STF integrals. This transformation is carried out using the  $B$ -spline expansion coefficients of the STFs. This accuracy check may be valid because the STFs should be accurately expanded with  $B$ -splines.<sup>19</sup>

Below, Section 2 provides theoretical aspects and the resulting approximated formulas of many-electron integrals. Section 3 explains computational aspects for the accuracy check. Section 4 discusses relative errors of the three- and four-electron integral values given from the approximated formulas to Ruiz's results.

## 2. THEORY

In this section, we present the formulas of approximated three- and four-electron integrals which appear in Hylleraas-CI calculations. To drive formulas of the integrals, we define a projection operator

$$p(1) = \sum_I |I(1)\rangle \langle I(1)| \quad (3)$$

using orthonormal functions  $\{I\}$ . The function  $I$  is written as

$$I(1) = i(1) Y_{l_I}^{m_I}(1), \quad (4)$$

where  $i$  is a radial function and  $Y_{l_I}^m$  is the spherical harmonics. Hereafter, the orthogonal functions that construct the projection operator  $p$  are written by  $I, J, K, \dots$ , and their radial functions are written by  $i, j, k, \dots$ . The summation of Eq.(3) is the simple notation as follows:

$$\sum_I \equiv \sum_{i=1}^N \sum_{l_I=0}^{\infty} \sum_{m_I=-l_I}^{l_I} . \quad (5)$$

The many-electron integrals are transformed by inserting the projection operators  $p$  between the inter-electronic distances, e.g.,

$$\langle ABC | r_{12}^s r_{13}^t r_{23}^u | A' B' C' \rangle = \langle ABC | r_{12}^s p(1) r_{13}^t p(2) p(3) r_{23}^u | A' B' C' \rangle \\ = \sum_{IJK} \langle AB | r_{12}^s | IJ \rangle \langle IC | r_{13}^t | AK \rangle \langle JK | r_{23}^u | B' C' \rangle. \quad (6)$$

Here,  $A, B, C, \dots$  are atomic orbitals, and their radial functions are written by  $a, b, c, \dots$ . All the radial functions in Eq.(6) are expanded with the  $B$ -splines. We simply write integrals by omitting electronic coordinate numbers of atomic orbitals; functions in the bra and the ket are arranged in order of the electronic coordinate number:

$$\langle ABC | r_{12}^s r_{13}^t r_{23}^u | A' B' C' \rangle = \langle A(1) B(2) C(3) | r_{12}^s r_{13}^t r_{23}^u | A'(1) B'(2) C'(3) \rangle. \quad (7)$$

The three- and four-electron integrals are transformed into sums of products of two-electron integrals using the projection operators  $p$ . First, we show transformed formulas of three-electron integrals. To this end, two projection operators  $p$  are inserted between inter-electronic distances. After some manipulation, the result is as follows:

$$\langle ABC | r_{12}^s r_{13}^t r_{23}^u | A' B' C' \rangle = \sum_{IJK} \langle AB | r_{12}^s | IJ \rangle \langle IC | r_{13}^t | AK \rangle \langle JK | r_{23}^u | B' C' \rangle \\ = \sum_{k_1=0}^{k_{1max}} \sum_{k_2=0}^{k_{2max}} \sum_{k_3=0}^{k_{3max}} \sum_{ijk} (ai, bj)_{k_1}^s (ai, ck)_{k_2}^t (bj, ck)_{k_3}^u \\ \times \sum_{l_1=\max(|k_1-l_A|, |k_2-l_A|)}^{\min(k_1+l_A, k_2+l_A)} \sum_{l_2=\max(|k_1-l_B|, |k_3-l_B|)}^{\min(k_1+l_B, k_3+l_B)} \sum_{l_3=\max(|k_2-l_C|, |k_3-l_C|)}^{\min(k_2+l_C, k_3+l_C)} \\ m = \max(-l_1, -l_2 + m_A + m_B, -l_3 + m_A + m_B) \quad l_1 = \max(|k_1-l_A|, |k_2-l_A|) \quad l_2 = \max(|k_1-l_B|, |k_3-l_B|) \quad l_3 = \max(|k_2-l_C|, |k_3-l_C|) \\ \times c^{k_1}(l_A m_A, l_1 m) c^{k_2}(l_A m_A, l_1 m) c^{k_3}(l_A m_A, l_1 m) \\ \times c^{k_1}(l_B m_B, l_2 m_B - m) c^{k_2}(l_B m_A + m_B - m, l_B m_B) \\ \times c^{k_2}(l_C m_C, l_3 m - m_A + m_C) c^{k_3}(l_3 m - m_A + m_C, l_C m_C) \quad (8)$$

with

$$(ab, cd)_k^n = \sum_{s=0}^{\left\lfloor \frac{n+1}{2} \right\rfloor} D_{ks}^n \int dr_1 \int dr_2 a(r_1) b(r_1) \frac{r_<^{k+2s}}{r_>^{k+2s-n}} c(r_2) d(r_2), \quad (9)$$

where is  $c^k(lm, lm')$  is Condon-Shortley coefficient and  $D_{ks}^n$  is the expansion coefficient of  $r_{12}^n$ .  $k_{1max}$  is  $s/2$  for even  $s$  values,  $\infty$  for odd  $s$  values.  $k_{2max}$  and  $k_{3max}$  are same as  $k_{1max}$ . Taking  $u=0$  yields the three-electron integral:

$$\begin{aligned}
\langle ABC | r_{12}^s r_{13}^t | A' B' C' \rangle &= \sum_{IJK} \langle AB | r_{12}^s | IB' \rangle \langle IC | r_{12}^t | A' C' \rangle \\
&= \sum_{k_1=|l_B-l_{B'}|}^{l_B+l_{B'}} \sum_{k_2=|l_C-l_{C'}|}^{l_C+l_{C'}} \sum_{ijk} (ai, bb')_{k_1}^s (a'i, cc')_{k_2}^t \\
&\times \sum_{l=\max(|k_1-l_A|, |k_2-l_A|)}^{\min(k_1+l_A, k_2+l_A)} c^{k_1}(l_A m_A, lm_A + m_B - m_{B'}) \\
&\times c^{k_1}(lm_A + m_B - m_{B'}, l_A m_A) c^{k_1}(l_B m_B, l_{B'} m_B) c^{k_2}(l_C m_C, l_{C'} m_{C'}) \tag{10}
\end{aligned}$$

Three-electron kinetic integrals are transformed inserting the projection operator  $p$  between inter-electronic distances and the kinetic operator. The resulting formulas are as follows:

$$\begin{aligned}
\langle ABC | r_{12}^s T_1 r_{13}^t | A' B' C' \rangle &= \sum_{IJK} \langle AB | r_{12}^s | IB' \rangle \langle I | T | J \rangle \langle JC | r_{12}^t | A' C' \rangle \\
&= \sum_{k_1=|l_B-l_{B'}|}^{l_B+l_{B'}} \sum_{k_2=|l_C-l_{C'}|}^{l_C+l_{C'}} \sum_{l=\max(|k_1-l_A|, |k_2-l_A|)}^{\min(k_1+l_A, k_2+l_A)} \\
&\times \sum_{ijk} (ai, bb')_{k_1}^s (i | T | j)_l (a'i, cc')_{k_2}^t \\
&\times c^{k_2}(l_A m_A, lm_A + m_B - m_{B'}) c^{k_1}(lm_A + m_B - m_{B'}, l_A m_A) \\
&\times c^{k_1}(l_B m_B, l_{B'} m_B) c^{k_2}(l_C m_C, l_{C'} m_{C'}) \tag{11}
\end{aligned}$$

and

$$\begin{aligned}
\langle ABC | r_{12}^s T_2 r_{13}^t | A' B' C' \rangle &= \sum_{IJ} \langle AB | r_{12}^s | IJ \rangle \langle J | T | B' \rangle \langle IC | r_{12}^t | A' C' \rangle \\
&= \sum_{k_1=|l_B-l_{B'}|}^{l_B+l_{B'}} \sum_{k_2=|l_C-l_{C'}|}^{l_C+l_{C'}} \sum_{ij} (ai, jb)_{k_1}^s (j | T | b')_{l_B} (a'i, cc')_{k_2}^t \\
&\times \sum_{l=\max(|k_1-l_A|, |k_2-l_A|)}^{\min(k_1+l_A, k_2+l_A)} c^{k_2}(l_A m_A, lm_A + m_B - m_{B'}) \\
&\times c^{k_1}(lm_A + m_B + m_{B'}, l_A m_A) c^{k_1}(l_B m_B, l_{B'} m_B) c^{k_2}(l_C m_C, l_{C'} m_{C'}) \tag{12}
\end{aligned}$$

where  $T$  is the kinetic operator:

$$T = -\frac{1}{2} \frac{d^2}{dr^2} + \frac{l(l+1)}{2r^2} \quad (13)$$

and  $(i|T|j)_l$  is a one-electron kinetic radial integral. Generally, computation of the three-electron kinetic integral is laborious. Eqs.(11) and (12) allow for easy and accurate computation of the approximated kinetic integral.

Approximated four-electron integrals are also derived in the similar way to the three-electron integrals as follows:

$$\begin{aligned} \langle ABCD | r_{12}^s r_{13}^t r_{34}^u | A' B' C' D' \rangle &= \sum_{IJ} \langle AB | r_{12}^s | IB' \rangle \langle IC | r_{12}^t | IC' \rangle \langle JD | r_{12}^u | C' D' \rangle \\ &= \sum_{k_1=|l_B-l_{B'}|}^{l_B+l_{B'}} \sum_{k_2=0}^{\infty} \sum_{k_3=|l_D-l_{D'}|}^{l_D+l_{D'}} \sum_{ij} (ai, bb')_{k_1}^s (a'i, cj)_{k_2}^t (c'j, dd')_{k_3}^u \\ &\times \sum_{l_1=\max(|k_1-l_A|, |k_2-l_A|)}^{\min(k_1+l_A, k_2+l_A)} c^{k_2}(l_A m_A, l_1 m_1) c^{k_1}(l_1 m_1, l_A m_A) \\ &\times \sum_{l_2=\max(|k_2-l_C|, |k_3-l_C|)}^{\min(k_2+l_C, k_3+l_C)} c^{k_2}(l_C m_C, l_2 m_2) c^{k_3}(l_C m_C, l_2 m_2) \\ &\times c^{k_1}(l_B m_B, l_{B'} m_{B'}) c^{k_3}(l_D m_D, l_{D'} m_{D'}) \end{aligned} \quad (14)$$

and

$$\begin{aligned} \langle ABCD | r_{12}^s r_{13}^t r_{14}^u | A' B' C' D' \rangle &= \sum_{IJ} \langle AB | r_{12}^s | IB' \rangle \langle IC | r_{12}^t | JC' \rangle \langle JD | r_{12}^u | A' D' \rangle \\ &= \sum_{k_1=|l_B-l_{B'}|}^{l_B+l_{B'}} \sum_{k_2=|l_C-l_{C'}|}^{l_C+l_{C'}} \sum_{k_3=|l_D-l_{D'}|}^{l_D+l_{D'}} \sum_{ij} (ai, bb')_{k_1}^s (ij, cc')_{k_2}^t (aj, dd')_{k_3}^u \\ &\times \sum_{l_1=|k_1-l_A|}^{k_1+l_A} \sum_{l_2=|k_3-l_{A'}|}^{k_3+l_{A'}} c^{k_2}(l_{A'} m_{A'}, l_2 m_{A'} + m_{D'} - m_D) \\ &\times c^{k_2}(l_2 m_{A'} + m_{D'} - m_D, l_1 m_A + m_B - m_{B'}) \\ &\times c^{k_1}(l_1 m_A + m_B - m_{B'}, l_A m_A) c^{k_1}(l_B m_B, l_{B'} m_{B'}) \end{aligned}$$

$$\times c^{k_2}(l_C m_C, l_{C'} m_{C'}) c^{k_3}(l_D m_D, l_{D'} m_{D'}). \quad (15)$$

Thus, the three- and four-electron integrals over the  $B$ -splines required for the Hylleraas-CI method are expressed as sums of products of two-electron integrals.

### 3. COMPUTATION

#### A. $B$ -splines

This work calculated all the two-electron integrals Eq.(9) and the one-electron kinetic integrals using the  $B$ -splines. The atomic radial function  $P(r)$  is expanded with the  $B$ -splines and enforces the boundary conditions  $P(0) = 0$  and  $P(R) = 0$ . Since the first and the last terms of the  $B$ -splines with  $K$ -fold multiple knots are nonzero at  $r = 0$  and  $r = R$ , respectively, they are removed from the basis function to satisfy the boundary conditions. Thus, we obtain  $N$ -term  $B$ -spline sets. We use the following two knot sequences with endpoints of  $K$ -fold multiplicity. Several methods that generate the knot sequence have been proposed by Gilbert and Bertoncini.<sup>20</sup> In atomic calculations, the knot sequence that concentrates near the nucleus is required because the atomic orbitals rapidly change near the nucleus. Hence, an exponential or a summational knot sequence is suitable for atomic calculations. The exponential knot sequence (EKS) is as follows:

$$R_1, R_1\alpha, R_1\alpha^2, \dots, R, \quad (16)$$

where  $\alpha = (R/R_1)^{1/(N-K+2)}$ ,  $R_1$  is the initial interval of the knot sequence. The other is as follows:

$$R_1, R_1(1 + \beta), R_1(1 + \beta + \beta^2), \dots, R. \quad (17)$$

Here,  $\beta$  is the parameter characterizing the distribution of the knots, and is chosen to satisfy the following condition:

$$R = R_1(1 + \beta + \beta^2 + \dots + \beta^{N-K+2}) \quad (\beta \geq 1). \quad (18)$$

This knot sequence is referred to as a ‘summational knot sequence’ (SKS).

In our previous work<sup>19</sup>, it was shown that the STF can be accurately expanded with a  $B$ -spline set. A STF can be expanded with an error of  $\sim 10^{-15}$  in a 100-term  $B$ -spline set with  $K = 15$ ,  $R = 60$  and  $10^{-4} \leq R_1 \leq 10^{-2}$ . This result was obtained for both EKS and SKS. Therefore, the present work used the parameters  $K = 15$ ,  $R = 60$  and  $R_1 = 10^{-5}, 10^{-4}, 10^{-3}$ , and  $10^{-2}$ .

#### B. Three- and four-electron integrals

The three- and four-electron integrals obtained from our approximated formulas are compared ones given by Ruiz<sup>15,17</sup>. The three- and four-electron integrals evaluated by Ruiz are as follows:

##### 1. Three-electron integral (EI3)

$$\langle ABC | r_{12}^s r_{13}^t | A' B' C' \rangle. \quad (19)$$

2. Three-electron kinetic integral (EI3K)

$$\langle ABC | r_{12} T_1 r_{13} | A' B' C' \rangle. \quad (20)$$

3. Four-electron integral type 1 (EI41)

$$\langle ABCD | r_{12} r_{13} r_{34}^{-1} | A' B' C' D' \rangle. \quad (21)$$

4. Four-electron integral type 2 (EI42)

$$\langle ABCD | r_{12} r_{13} r_{14}^{-1} | A' B' C' D' \rangle. \quad (22)$$

Here,  $A, B, C$ , and  $D$  are STFs with exponential parameters  $\zeta$ , e.g.,

$$A \equiv r_i^{n_i-1} e^{-\zeta_i r_i} Y_{l_i}^{m_i}(\theta, \varphi). \quad (23)$$

The exponential parameter of  $A'$  is written by  $\zeta'_i$ . We define  $\omega_i \equiv \zeta_i + \zeta'_i$ . In this work, the radial part of STFs is expanded with the  $B$ -spline set as follows:

$$r^n e^{-\zeta r} \approx \sum_{i=2}^{N+1} C_i^{n,\zeta} B_{i,K}(r), \quad (24)$$

where  $C_i^{n,\zeta}$  are linear expansion coefficients.  $C_i^{n,\zeta}$  were determined by solving the system of linear equations:

$$\sum_{j=2}^{N+1} \left[ \int_0^R dr B_{i,K}(r) B_{j,K}(r) \right] C_j^{n,\zeta} = \int_0^R dr B_{i,K}(r) r^n e^{-\zeta r}, \quad (i = 2, \dots, N+1). \quad (25)$$

All the integrals were calculated by the Gauss integration procedure. The radial functions that construct the projection operator  $p$  were the functions obtained by dividing the eigenfunctions of the overlap matrix  $\mathbf{S}$  by the square root of its eigenvalues; the matrix element of  $\mathbf{S}$  is

$$(\mathbf{S})_{i-1,j-1} = \int_0^R dr B_{i,K}(r) B_{j,K}(r), \quad (i, j = 2, \dots, N+1). \quad (26)$$

#### 4. RESULTS AND DISCUSSION

In Section 2, we showed the approximated many-electron integral formulas with  $B$ -splines which appear in Hylleraas-CI calculations. The approximated many-electron integrals require radial two-electron integrals  $(ai, bj)_\lambda^s$ ,  $(ab, ij)_\lambda^s$ , and  $(ai, bc)_\lambda^s$ . These radial two-electron integrals must be stored. The remarkable feature of this work is that the approximated three-electron kinetic integrals were obtained. The computational formulas of three-electron kinetic integrals over  $B$ -splines are very complicated. This work transformed a three-electron kinetic integral into sums of products of two-electron integrals and a one-electron kinetic integral. Hence, three-electron kinetic integrals can be

easily computed by our formulas.

Table 1 summarizes averaged relative errors of our EI3, EI3K, EI41, and EI42 values to the Ruiz's values<sup>15,17</sup>. Only the error in the EI3K value of the charge distribution ( $3d_13d_1$ ,  $2p_12p_1''$ ,  $3d_13d_1''$ ) is very large. This value given by Ruiz is probably incorrect. The averaged relative errors of EI3K were calculated excluding this value. It should be noted that the errors arise not only from the construction of the projection operator  $p$ , but also from the approximation of the STFs. The averaged relative errors are large at  $R_1 = 10^{-5}$  for both EKS and SKS. The averaged relative error depends on  $R_1$  and is larger for smaller  $R_1$  value. This is because a knot sequence with small  $R_1$  value is concentrated near the nucleus and sparse away from the nucleus. The present comparison shows that the  $B$ -spline set on the SKS with  $R_1 = 10^{-2}$  and  $R = 60$  causes small relative errors ( $\sim 10^{-14}$ ). Since the error of approximation using the  $B$ -splines of STFs is  $\sim 10^{-15}$ , the approximation using the  $B$ -splines of the projection operator  $p$  is accurate.

Table 1. Averaged relative errors of EI3, EI3K, EI41, and EI42 to Ruiz's values.

$R_1$	$10^{-5}$	$10^{-4}$	$10^{-3}$	$10^{-2}$
<b>EI3</b>				
EKS	8.55E-12	3.39E-13	3.67E-14	5.04E-14
SKS	4.99E-13	6.19E-14	2.57E-14	1.54E-14
<b>EI3K</b>				
EKS	5.23E-12	3.57E-14	4.45E-14	6.55E-14
SKS	4.44E-14	5.98E-14	3.21E-14	2.50E-14
<b>EI41</b>				
EKS	3.61E-12	1.60E-13	3.96E-14	4.07E-14
SKS	1.97E-13	4.88E-14	3.26E-14	2.11E-14
<b>EI42</b>				
EKS	3.93E-12	1.68E-13	4.52E-14	4.70E-14
SKS	2.15E-13	3.35E-14	2.79E-14	2.10E-14

Tables 2, 3, 4, and 5 respectively summarize EI3, EI3K, EI41, and EI42 values together with Ruiz's values. Our integrals are calculated using the EKS with  $R_1 = 10^{-3}$  and the SKS with  $R_1 = 10^{-2}$ . These knot sequences give results with small errors. Above mentioned, the EI3K value of the charge distribution ( $3d_13d_1$ ,  $2p_12p_1''$ ,  $3d_13d_1''$ ) given by Ruiz is probably incorrect. The other integrals are in good agreement with our integrals. In Ruiz's EI41 and EI42 tables, the charge distribution ( $3d_{-2}3f_0$ ,  $4f_14d_{-1}$ ,  $4d_14d_{-1}$ ,  $4d_{-2}4f_0''$ ) is incorrect for ( $3d_{-2}3d_0$ ,  $4f_14f_{-1}$ ,  $4d_14d_{-1}$ ,  $4d_{-2}4f_0''$ ).

Table 2. Comparison of EI3 values: the charge distributions are constructed with the exponents  $\zeta = 1.40$  for STFs with ", otherwise  $\zeta = 2.86$ .

There is the other approximation of three-electron integrals. It is method that constructed by sums of products of two-electron kinetic integrals and two-electron integrals:

$$\langle ABC | r_{12}^s T_1 r_{13}^t | A' B' C' \rangle = \sum_I \langle AB | r_{12}^s | IB' \rangle \langle IC | T_1 r_{12}^t | A' C' \rangle. \quad (27)$$

This approximated formula requires the two-electron kinetic integrals. Eq.(27) may be calculated more accurate than Eq.(11).
